

INVESTOR IN PEOPLE

The Patent Office
Concept House
Cardiff Road
Newport
South Wales
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 01645 500505
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

SELF-SERVICE TERMINAL

The present invention relates to a self-service terminal (SST) and to a method of operating an SST. In particular, the invention relates to an automated teller machine (ATM), and to a method of operating an ATM.

5 ATMs provide users with a convenient source of cash in an unattended environment. However, to benefit from this convenience a user must be able physically to access an ATM, and must also be able to input data requested by the ATM such as a personal identification number (PIN), an amount of
10 cash to be withdrawn, and such like data. As a result, certain people are not able to use ATMs, for example, because they are confined to a home, because they have a visual impairment, because an ATM is located in an area that is not physically accessible for them, or such like reason.

15 To overcome this problem, some people entrust their ATM card and PIN to a third party for conducting transactions on their behalf; but this is undesirable because it may lead to fraud, for example, if the third party withdraws more money than they are asked to withdraw, or if the third party makes
20 unauthorised withdrawals.

It is among the objects of an embodiment of the present invention to obviate or mitigate one or more of the above disadvantages, or other disadvantages associated with conventional SSTs.

25 According to a first aspect of the present invention there is provided a self-service terminal having a user interface including means for identifying a user, characterised in that the terminal includes means for obtaining contact information for a communications device
30 associated with a user; and contact means for establishing a

link with the communications device to allow a transaction to be entered thereby.

Preferably, an entire transaction is entered using the communications device, where an entire transaction includes entry of an identification, such as a PIN, and entry of transaction data, such as an amount of money to be withdrawn.

The communications device is retained by a user, and is used as an alternative to any input device on the SST, such as a keypad, touchscreen, function display keys (FDKs), or such like. Thus, the communications device is used as an alternative input means.

In one embodiment, the communications device is located remotely from the SST during a transaction. This allows a person ("the user") to enter a transaction at a remote location while another person, who is located at the SST, receives any item dispensed from the SST as a result of the transaction entered by the user.

By virtue of this embodiment of the invention an account holder ("the user") who is unable to access or use an ATM is able to provide a third party with a token that the third party presents to the ATM. The account holder ("the user") is contacted by the ATM when a transaction is to be entered. The account holder can then enter a security code (such as a PIN) and transaction details (such as withdraw twenty pounds sterling). This enables an account holder to allow a third party to collect money or other media from their account using an ATM, without having to divulge a PIN or other security code to the third party, thereby minimising the potential for abuse of trust.

In another embodiment, the communications device is located locally at the SST during a transaction so that the person who operates the communications device ("the user") is the person who receives any item dispensed from the SST
5 as a result of the transaction.

By virtue of this embodiment of the invention, a self-service terminal is operable to identify a user and to dial a user's telephone so that the user can enter a transaction using the telephone rather than the terminal's user
10 interface. One advantage of this embodiment of the invention is that the user does not have to determine the telephone number of the SST, because the SST calls the user's communications device once the user has been identified. For a visually-impaired user who has no
15 difficulty in physically accessing an SST, this obviates any requirement for a third party to assist with a transaction.

It will be appreciated that "the user" referred to herein is the person who operates the communications device, not necessarily the person who is located at the SST.

20 Preferably, the communications device is in the form of a telephone, such as a cellular telephone (for use in entering a transaction either locally at an SST or remotely from an SST) or a landline telephone (for use in entering a transaction remotely from an SST). Alternatively, the
25 communications device is in the form of a computing device having a modem. Typical computing devices include a personal computer (PC), a pocket computer, a personal digital assistant, and such like.

Preferably, the means for identifying a user comprises
30 a module (such as a card reader) for receiving a physical identification token (a claimed identity), which is used in conjunction with an identity verifier, such as a personal

identification number (PIN). Suitable card readers include a magnetic stripe card reader and a smart card reader. Other identification tokens may be used, such as a smart ring, smart button, personal digital assistant, or cellular
5 telephone. Alternatively, in embodiments where the user is always located in the vicinity of the SST, the means for identifying a user may comprise a recognition module (such as a biometrics unit) for receiving a token derived from part of a user's body. Suitable biometrics units include a
10 human iris recognition unit, a fingerprint sensing unit, a facial recognition unit, a voice recognition unit, and such like.

The means for obtaining contact information for a communications device associated with a user may be
15 implemented by a controller accessing a database of stored telephone numbers. Alternatively, the telephone number may be retrieved from a user identification token (for example, the telephone number may be stored on a user's card), so the means for obtaining contact information may be implemented
20 by a token reader (such as a card reader).

The database stores a user identifier and a telephone number or numbers associated with that user. Where more than one telephone number is stored, an algorithm or rules engine may be used to determine which number is to be
25 called, or the numbers may be called in a predetermined order or in an order determined by the rules engine.

The database may be stored on the SST, partially on the SST (for example, in a distributed storage arrangement), or in a remote repository.

30 The contact means may contact the communications device directly, for example, by dialling a telephone number associated with the communications device. Alternatively,

the contact means may contact the communications device indirectly, for example, by requesting a remote centre to contact the communications device. The remote centre may be a transaction host.

5 The contact means may be implemented by a transceiver, such as a cellular radio-frequency transceiver.

 The self-service terminal may be an ATM.

 According to a second aspect of the present invention there is provided a method of operating a self-service
10 terminal having a user interface, the method including the step of identifying a user, and being characterised by the further steps of: obtaining contact information for a communications device associated with the identified user, and establishing a telecommunications link with the
15 communications device so that a transaction may be entered via the link.

 The step of identifying a user is preferably implemented by receiving an identity token. An identity verifier, such as a PIN or code, may be requested by the
20 terminal after the link has been established so that the person presenting the claimed identity does not need to be aware of the identity verifier.

 According to a third aspect of the present invention there is provided a self-service terminal system comprising
25 a host and at least one self-service terminal, each terminal having a user interface including transaction entry means and means for identifying a user, characterised in that the system includes means for obtaining contact information for a communications device associated with a user, and contact
30 means for contacting the communications device to allow a transaction to be entered thereby.

According to a fourth aspect of the present invention there is provided a self-service terminal for visually impaired users, the terminal comprising means for identifying a user, and means for contacting a communications device associated with that user, whereby a user may operate the terminal using the communications device.

According to a fifth aspect of the present invention there is provided a self-service terminal having a user interface including transaction entry means and a token reader for reading an identification token, characterised in that the terminal is operable to read a token indicating that a transaction is to be entered using remote entry means, and includes contact means for contacting the remote entry means to allow a transaction to be entered thereby.

These and other aspects of the present invention will be apparent from the following specific description, given by way of example, with reference to the accompanying drawings, in which:

Fig 1 is a block diagram of a self-service terminal system according to one embodiment of the present invention;

Fig 2 is a schematic perspective view of one of the terminals of Fig 1;

Fig 3 is a simplified block diagram of the architecture of the terminal of Fig 2;

Figs 4a to 4d illustrate screens presented to a person located at one of the terminals of Fig 1 during a transaction;

Fig 5 is a block diagram of a self-service terminal system according to another embodiment of the present invention; and

Fig 6 is a simplified block diagram of the architecture of the terminal of Fig 5.

Reference is now made to Fig 1, which is a block diagram of a self-service terminal system 10 according to one embodiment of the present invention. The system 10 is owned and operated by a financial institution and comprises a host 12 interconnected to a plurality of SSTs 14 (only two, 14a and 14b, are shown) by a secure network 16. The SSTs 14 are ATMs. The host 12 includes a communication interface 17, an authorisation facility 18 and a back-office facility 20.

The authorisation facility 18 authorises transaction requests received from ATMs via the network 16. The authorisation facility 18 also authorises transaction requests received from Point of Sale terminals (not shown) and other ATM networks (not shown).

The back-office facility 20 maintains records for every account maintained by the financial institution. Each record includes a list of all the transactions executed relating to that account. Typical transactions include: direct credits, direct debits, cheques, cash withdrawals, and such like. The back-office facility 20 provides (typically on a daily basis) the transaction authorisation facility 18 with account information for each account maintained by the financial institution.

The ATMs 14 are physically remote from each other, but are shown in proximity in Fig 1 for clarity. Fig 1 also shows a remote entry means 21 (also referred to herein as a communications device) in the form of a cellular telephone which can be accessed by the communication interface 17, as described in more detail below.

Reference is now made to Fig 2, which is a perspective view of one of the ATMs 14 of Fig 1. Each ATM 14 has a user interface 22 located within a moulded fascia 24. The user interface 22 comprises: a display 26, local entry means 28
5 in the form of an encrypting keypad, a cash dispense slot 30, a card entry/exit slot 32, and a receipt slot 34.

Reference is now made to Fig 3, which is a simplified block diagram of the architecture of the terminal of Fig 2. A system bus (or a plurality of system buses) 36
10 interconnects various modules in an ATM controller 40 to allow mutual intercommunication, as will be described in more detail below.

User associated modules 42 comprise the following elements (peripheral devices): a token reader 50 in the form
15 of a card reader, the display 26, the encrypting keypad module 28, a printer 56, and a cash dispenser 58. Some of these user associated modules 42 are part of the user interface 22 (such as the display 26 and the keypad 28), other user associated modules 42 are associated with the
20 user interface 22 (such as the card reader 50, which is associated with, and located rearwardly of, the card entry/exit slot 32).

The controller 40 comprises modules for driving the user interface elements, namely: card reader controller 60,
25 display controller 62, keypad controller 64, printer controller 66, and dispenser controller 68. These user associated modules (26, 28, 50, 56, and 58) and associated controllers (60 to 68) are standard modules that are used in conventional ATMs and will not be described in detail
30 herein.

The controller 40 also comprises a BIOS 70 stored in non-volatile memory, a microprocessor 72, associated main

memory 74, storage space 76 in the form of a magnetic disk drive, and a dedicated network connection 78 for connecting the ATM 14 to the transaction host 12 (Fig 1) via the network 16.

5 In use, the main memory 74 is loaded with an ATM operating system kernel 80, and an ATM application 82. As is well known in the art, the operating system kernel 80 is responsible for memory, process, task, and disk management. The ATM application 82 is responsible for controlling the
10 operation of the ATM 14, including: presenting screens on the ATM display 26, receiving data read by the card reader 50, preparing transaction requests for sending to the host 12 via the network connection 78, and receiving responses and commands from the host 12 via the network connection 78.

15 The term "screen" is used herein to denote the graphics, text, controls (such as menu options), and such like, that are displayed on an ATM monitor; the term "screen" as used herein does not refer to the hardware (that is, the monitor) that displays the graphics, text, controls,
20 and such like.

 If a person is unable to use an ATM or experiences difficulty in using an ATM, for example because of mobility problems or visual impairment, then that person provides the financial institution with a contact telephone number to be
25 used during a transaction. The institution then issues that person (the account holder, also referred to herein as "the user") with a magnetic stripe card that stores a contact telephone number in addition to conventional details about the account holder and the account. The contact telephone
30 number is the telephone number of the account holder's cellular telephone 21.

Two person transaction example

One example of a typical transaction at one of the ATMs 14 will now be given with reference to Figs 4a to 4d. In this example, the account holder wishes to withdraw cash from an ATM, and gives the card to a trusted third party, 5 for example a friend or relative. Thus, in this example, the person entering transaction details is located remotely from the ATM 14, and a trusted third party is used to initiate the transaction at the ATM 14.

Initially, the third party approaches an ATM 14 10 displaying screen 100 (Fig 4a) and inserts the card. The card reader 50 reads the magnetic stripe on the card and conveys the read details to the ATM application 82 via the card reader controller 60 and the bus 36. The ATM application 82 analyses these details and determines that 15 the magnetic stripe stores a telephone number in addition to account details (for example, name of account, number of account, and such like).

The ATM application 82 displays screen 102 (Fig 4b) to inform the person located at the ATM (in this example, the 20 third party) that the transaction will be entered using a remote entry device (that is, not using the ATM's user interface 22).

The ATM application 82 then uses network connection 78 to convey a file including account details and the telephone 25 number to the communication interface 17 in host 12. The communication interface 17 receives this file and automatically dials the telephone number and activates an audio and/or visual interface. This embodiment uses an audio interface having recorded messages and selectable 30 options associated with numbers so that a user can select an option by depressing a number on the telephone keypad.

When the account holder answers this telephone call at the cellular telephone 21, then the account holder is first asked (by the audio interface) to enter a secure code. The secure code may be the account holder's PIN, or it may be
5 another code (referred to herein as an access code). The access code may be a subset of a longer code. For example, the account holder may be asked to enter the second, fourth, and fifth digits/letters of their access code. This may be used to improve security in case a fraudster attempts to
10 eavesdrop or intercept a code as it is being entered by the account holder.

Once the account holder has entered the secure code, a transaction menu is then recited to the account holder. The transaction menu may include options such as: bill payment,
15 cash withdrawal, transfer funds between accounts, and such like.

In this example, the account holder selects the cash withdrawal option, using either speech or a button on the telephone 21.

20 A cash withdrawal menu is then recited to the account holder. The account holder enters the amount of cash to be withdrawn. A confirmation menu may also be recited to allow the account holder to confirm the transaction details.

The communication interface 17 then combines the
25 transaction details and code entered by the account holder with the account details conveyed from the ATM 14 into a single transaction request file and sends the transaction request file to the authorisation facility 18 for authorising.

30 If the transaction request is authorised then the host 12 notifies the ATM 14 and the ATM application 82 presents a

screen 104 (Fig 4c) to the person located at the ATM (in this example, the trusted third party) to inform him/her to remove the card because cash is about to be dispensed.

5 The communication interface 17 may also inform the account holder via cellular telephone 21 that the transaction has been executed and that cash has been dispensed.

If the transaction request is not authorised, for example, because the secure code was incorrect or because
10 adequate funds are not available, then the ATM application 82 presents a screen 106 (Fig 4d) to the trusted third party to inform him/her that the transaction was not authorised.

The communication interface 17 may also inform the account holder via cellular telephone 21 that the
15 transaction has not been authorised.

It will be appreciated that this embodiment has the advantage that an account holder can execute a transaction at an ATM without having to be present at the ATM, and without having to divulge their PIN or other secure code to
20 enable the transaction to be executed, thereby reducing the possibility of fraud. It will also be appreciated that this embodiment has the advantage that an account holder can control a transaction in real time even though the account holder is located remotely from a terminal that fulfils the
25 transaction.

It will also be appreciated that in the above embodiment the means for obtaining contact information for a communications device and the means for identifying a user are both implemented by the card reader 50 in conjunction
30 with the card reader controller 60 and the ATM application 82.

One person transaction example

Another example of a typical transaction at one of the ATMs 14 will now be given. In this example, the person conducting a transaction is located in the immediate vicinity of the ATM 14, and initiates the transaction at the ATM 14 by inserting the card.

The transaction proceeds in the same way as the above example, the only differences being that the account holder is present at the ATM, and the account holder removes the withdrawn cash.

Second embodiment

Another embodiment of the present invention will now be described with reference to Fig 5, which is a block diagram of a self-service terminal system 210 according to another embodiment of the present invention; and also with reference to Fig 6, which is a simplified block diagram of the architecture of the terminal of Fig 5.

The system 210 is owned and operated by a financial institution and comprises a host 212 interconnected to a plurality of SSTs 214 (only two, 214a and 214b, are shown) by a secure network 16. The SSTs 214 are ATMs. The host 212 includes an authorisation facility 18 and a back-office facility 20.

The ATMs 214 are similar to ATMs 14; but the ATM controller 240 in ATMs 214 is slightly different to the ATM controller 40 in ATMs 14. In particular, ATM controller 240 includes contact means 217 in the form of a transceiver, and a modified ATM application 282.

In this embodiment, an ATM 214 communicates directly with a communications device 21 rather than via the communication interface 17. This is accomplished by the

transceiver 217 dialling (under control of the ATM application 282) the communications device 21 and conveying data between the ATM application 282 and the communications device 21. When the ATM application 282 has received from
5 the communications device 21 all data required for a transaction, the ATM application 282 obtains authorisation for the transaction from the remote host 212 in a conventional manner.

10 In a similar way as for the previous embodiment (Figs 1 to 4D), this embodiment can be used by an account holder who is present at the ATM during a transaction (the one person transaction example), or by an account holder who is remote from the ATM during a transaction (the two person transaction example).

15 Various modifications may be made to the above described embodiments within the scope of the invention, for example, the communications device 21 may include an encryption unit for increased security. In other embodiments, the ATM application 82 or 282 may present the
20 trusted third party with advertisements during the delay introduced by the account holder entering a transaction. In other embodiments, the person entering the transaction may be enabled to stop presentation of screens at the ATM while a transaction is being entered and executed. In other
25 embodiments, the SST may be a non-cash kiosk.

Claims

1. A self-service terminal (14 or 214) having a user interface (22) including means (50) for identifying a user, characterised in that the terminal includes means (50) for
5 obtaining contact information for a communications device associated with a user; and contact means (17 or 217) for establishing a link with the communications device (21) to allow a transaction to be entered thereby
2. A terminal according to claim 1, wherein the
10 communications device (21) is a telephone.
3. A terminal according to claim 2, wherein the means for obtaining contact information includes means for retrieving data relating to a telephone number to be called by the terminal to contact the telephone.
- 15 4. A terminal according to any preceding claim, wherein the contact means contacts the communications device directly.
5. A terminal according to any of claims 1 to 3, wherein the contact means requests a remote transceiver to
20 establish a link with the communications device.
6. A terminal according to any preceding claim, wherein the terminal is an automated teller machine.
7. A method of operating a self-service terminal having a user interface, the method including the step of
25 identifying a user, and being characterised by the further steps of: obtaining contact information for a communications device associated with the identified user, and establishing a telecommunications link with the communications device so that a transaction may be entered via the link.

8. . . A self-service terminal system (10 or 210)
comprising a host (12 or 212) and at least one self-service
terminal (14 or 214), each terminal (14 or 214) having a
user interface (22) including transaction entry means (28)
5 and means (50) for identifying a user, characterised in that
the system (10 or 210) includes means (50) for obtaining
contact information for a communications device (21)
associated with a user, and contact means (17 or 217) for
contacting the communications device (21) to allow a
10 transaction to be entered thereby.

SELF-SERVICE TERMINAL

Abstract

A self-service terminal (14 or 214) is described. The terminal has a user interface (22) including transaction entry means (28) and a token reader (50) for reading an identification token. The terminal (14 or 214) is operable
5 to read a token indicating that a transaction is to be entered using a communications device (21), such as a telephone. The terminal further includes contact means (78,82 or 217,282) for contacting the communications device (21) to allow a transaction to be entered thereby. A method
10 of operating a self-service terminal, and a self-service terminal system, are also described.
